Abstract—This paper presents the design of an electronic stability control (ESC) system based on trailer differential braking for increasing safety and improving handling performance of car-trailer combinations. Numerical simulations were performed using CarSim software to assess the performance of the proposed control strategies of the ESC system. To validate the virtual design of the ESC system for car-trailer combinations, a small scaled physical prototype (1:10) of a car-trailer combination was fabricated and tested. The prototype consists of an aluminum frame, accelerometer, and two wheels equipped with an electromagnetic differential braking. Numerical simulation and prototype testing demonstrated the effectiveness of the proposed ESC system for car-trailer combinations.

Keywords: electronic stability control; lateral acceleration; differential braking; car-trailer combination

I. INTRODUCTION

Car-trailers are easy to own recently for several reasons, such as, their low cost, availability, and simplicity of the design. However, trailer safety systems and technology are outdated and not increasing at the same rate as passenger vehicles. For example, in Ontario, towing a trailer with a gross vehicle weight of up to 4,600 Kilograms does not require a higher driving license class. In addition, the Ministry of Transportation of Ontario does not have any regulations regarding the braking system required to ensure the safety of the trailer [1].

Car trailers usually face two of the most dangerous scenarios, known as sway and jackknifing [2]. In addition, rollovers have a huge impact on the trailer’s stability. Rollovers occur due to different reasons such as; high speeds, crosswinds, road conditions and center of gravity of the trailer, which could be, affected by the way the trailer was loaded.

Understanding why each of sway, jackknifing and rollovers occur will result in an effective robust ESC controller. First, sway is defined as the unusual lateral motion that the trailers go through due to several reasons, such as; side passing wing on open roads, bow wind produced by commercial vehicles and firstly, the load distribution inside the trailer which has an effect on the tongue load. Moving sideways will result in pendulum motion [3], which cause the car-trailer combination to lose stability. Load distribution has an impact on the braking distribution force, as the trailer could lose traction and gripping the road, which allows the trailer to swing and skid [4].

The second major hazard is the rollover, which happens due to sharp turns, high speeds and load distribution. Rollover often occurs when the lateral acceleration of the trailer is larger than the threshold value.

Jackknifing is the third major unstable motion mode. Jackknifing may be caused by several factors, such as momentum of the combination, weather condition, and low friction of road surfaces [5].

To address the aforementioned problems and avoid severe accidents, conventional braking systems may be enhanced by introducing active trailer differential braking systems. An electronic stability control system (ESC) is developed as an important safety feature in passenger vehicles. ESC is an active safety technology that improves the vehicle’s stability by assisting the driver to keep the car-trailer combination on the desired path [6].

To implement the functionality of ESC, several vehicle dynamic states can be controlled, such as yaw rate of vehicle units [7], lateral motions of vehicle units [8]. Each of the above mentioned methods requires a car-trailer combination equipped with several sensors to ensure a responsive and accurate system.

Lateral acceleration control has been used for the design of active trailer differential braking system. A small-scale prototype was fabricated and examined to validate the active trailer differential braking system designed in this project, and the lateral-acceleration rearward amplification (RWA) was used as an essential lateral stability measure of the car-trailer combination [9]. Controlling the lateral acceleration of the vehicle units may effectively prevent the occurrence of rearward amplification, in which the trailer has a greater lateral acceleration than the leading unit, which can lead to rollover of the trailer [10].
II. DESIGN OF AN ACTIVE TRAILER DIFFERENTIAL BRAKING SYSTEM

The design of the electronic stability control (ESC) system involves the modeling of the car-trailer system for controller design, a small-scaled physical prototype fabrication, and performance evaluation. The design process may be divided into two different phases. The first is the design of a virtual prototype, while the second phase is the fabrication of the small-scaled physical prototype to validate the virtual design.

A. Mathematical Modeling

As shown in Fig. 1, 3 degrees of freedom (DOF) yaw-plane car-trailer model is generated for the ESC controller design.

![Schematic representation of the 3 DOF yaw-plane car-trailer model and the parameters used [11].](image)

The equations of motion of the leading vehicle are expressed as follows [11]:

\[
m_1(\ddot{\theta} - Vr) = -X_1 \cos \delta - X_2 + X
\]

(1)

\[
m_1(\dot{V} + ur) = f_1(\alpha_1) + f_2(\alpha_2) + X_1 \sin \delta - Y
\]

(2)

\[l_1 \dot{r} = a f_1(\alpha_1) - b f_2(\alpha_2) + a X_1 \sin \delta + dY
\]

(3)

The trailer’s equations of motion are expressed as [11]:

\[
m_2(\ddot{\theta}' - V'r') = -X_3 - Y \sin \psi - X \cos \psi
\]

(4)

\[
m_2(\dot{V}' + u'r') = f_3(\alpha_3) + Y \cos \psi - X \sin \psi
\]

(5)

\[l_2 \dot{r}' = -h f_3(\alpha_3) - e(-Y \cos \psi + X \sin \psi)
\]

(6)

Due to fact that the trailer is connected to the leading vehicle with an articulated joint, the forward velocity and acceleration of the leading and trailing units are assumed the same. This assumption simplifies the trailer equations of motion and helps linearize them.

In addition, the angle \(\psi\) is approximated to be small, which leads to [11]:

\[\cos(\psi) = 1\]

(7)

\[\sin(\psi) = \psi\]

(8)

Also, the following equation is determined at zero initial conditions [11]:

\[\psi = r - r'\]

(9)

Using all the above assumptions and approximations, a linearized equation of motion can be expressed as [11]:

\[M(\dot{x}) + D(x) + F\delta = 0\]

(10)

where the state variables are written as shown in “(11)” [11]:

\[\{x\} = \{V r \dot{\psi} \psi\}\]

(11)

Matrices \(M, D\) and \(F\) are listed in Appendix A.

The parameters listed in Table 1 are used in the mathematical modeling and CarSim model generation.

Equations (1) to (11) show how to express a mathematical model of a car-trailer combination with some assumptions to linearize the system. However, the trailer differential braking system is designed to generate a counter moment to stabilize the car-trailer combination [10], which will result in the shown equation [11]:

\[l_2 \dot{r}' = -h f_3(\alpha_3) - e(-Y \cos \psi + X \sin \psi) + \Delta M_x\]

(12)
Using the same approximations and assumptions, the governing equations of motion of the car-trailer can be linearized and simplified as the following form [11]:

\[ M\ddot{x} + D\dot{x} + C_B u + F\delta = 0 \]  

(13)

where,

\[ u = -K_p \cdot \dot{\alpha}_y \]  

(14)

The lateral acceleration of the trailer (\(\dot{\alpha}_y\)) can be formulated using mathematical manipulations and operations. However, an accelerometer sensor was used to measure the lateral acceleration of the physical prototype.

**B. ESC Controller Design**

There are several types of control techniques that can be used to design an ESC system, such as, PID and LQR [12]. The purpose of this research is not only to design an ESC controller but also to fabricate a small-scaled car-trailer prototype equipped with the ESC system. Thus, a feasible ESC controller is designed. A P-control scheme is used for simplicity of tuning, proving the concept design, and fabricating a small-scaled car-trailer prototype with the ESC. The block diagram of the controller design is shown in Fig. 2, representing the P-control scheme.

The virtual car-trailer prototype with the ESC system is designed and tested using CarSim software package. CarSim provides various vehicle and trailer models that could be used to simulate selected testing maneuvers.

Since the trailer is the focus of the research, the ESC controller designed in Matlab was integrated in the car-trailer model developed in CarSim. The designed ESC is built upon the existing Anti-Locking Braking System (ABS) of trailers. The ESC controls the right and left brakes of the trailer independently. This is known as differential braking [13]. Differential braking is used to control the yaw moment, which affects the lateral acceleration of the trailer. To ensure that the ESC is functioning as desired, several testing maneuvers are simulated, such as a double lane change maneuver.

**C. Virtual Car-Trailer Prototype with the ESC system**

The virtual car-trailer prototype with the ESC system is designed and tested using CarSim software package. The car-trailer block in CarSim exports the lateral acceleration of the leading vehicle and the trailer into the P-Controller based ESC system. The controller multiplies the input by the gain \(K_p\), and then a generated brake pressure value is sent back to the car-trailer block to apply brakes on a specific wheel. This process continues until the error between the desired and actual lateral accelerations is minimized. The ESC controller is designed to meet the requirements of a differential braking where brakes are applied on each wheel independently. In addition, the controller applies braking force in form of brake pulsing to prevent wheels from locking.

**D. Small-Scaled Physical Car-Trailer Prototype with the ESC System**

Once all the results are justified based on the numerical results of the virtual car-trailer prototype with the ESC system, a 1:10 small-scaled physical car-trailer prototype with the ESC system is designed and fabricated. The purpose of building the physical prototype is to conduct similar tests that have been done in CarSim and to compare the performance measures derived from both cases.

Since the physical prototype is equipped with a P-controller, a microcontroller is required on board. An Arduino Uno is used as the brain of the module to simulate all the data gathered by the accelerometer. The designed ESC is stored in the microcontroller to apply the required braking force based on the input of the lateral acceleration. In addition, the fabricated trailer is equipped with differential braking using two electromagnetic brakes. Fig. 4, shows the fabricated prototype with all the mentioned components needed to achieve a functional ESC.
III. RESULTS AND DISCUSSION

As mentioned earlier, the car-trailer model developed in CarSim is used to simulate the double lane change maneuver to test the effectiveness of the designed ESC. A representation of double lane change maneuver can be seen in Fig. 5.

The first test is done using the combination of a car towing a trailer, which is not equipped with an ESC. The Fig. 6, shows the graphs representation of the lateral acceleration over time.

By looking at the graph in Fig. 6, the blue line represents the lateral acceleration of the leading vehicle which gets affected by the trailer in similar scenarios, such as double lane change maneuver, whereas the orange line represents the lateral acceleration of the trailer. It is concluded that the trailer’s reaction has a time delay and then the combination lost stability. In addition, it is also determined that the trailer has a higher lateral acceleration at all times which means the trailer has a larger sway rate than the leading car which results in losing control over the combination.

To examine the system, the same test is done. However, the car-trailer combination is now equipped with the designed ESC. Fig. 7, represents the lateral acceleration over time of the leading vehicle and trailer with the ESC controller.

By looking at the plots in Fig. 7, the blue curve represents the response of the leading vehicle, where the orange curve represents the trailer’s behavior. It is observed that the combination has its lateral acceleration peaks at the turning points. As expected, the trailer has a larger lateral acceleration compared to the leading vehicle. However, the combination does not lose stability and sway is controlled. By looking at the graph between time intervals of 7-18 seconds, the combination has a minor oscillation and that was due to the use of P-controller.

By comparing the behavior of controlled and uncontrolled combination, we conclude that the trailer’s lateral acceleration has an impact on the leading vehicle as it loses stability in the first case when the trailer loses stability. In addition, the lateral acceleration of leading vehicle and trailer have a larger amplitude when the combination is not equipped with a controller.

As stated previously, the testing phase for the physical prototype defers from the virtual prototype. To compare the results of the virtual and physical prototype, two test have been done using the physical prototype. To exert graphs from the physical prototype, a gyroscope is used to calculate the articulation angle between the leading vehicle and the trailer with reference to the leading car. Fig. 8, shows the representation of the articulation angles over time in both controlled and uncontrolled situations based on the testing results using the small-scaled physical car-trailer prototype.
el. The ESC controller designed in Matlab is then fabricated. In both virtual and physical prototype tests, the ESC improves the stability by controlling the yaw moment of the combination. Although the results based on the P-control scheme are promising, an advanced control scheme for the ESC could be used to further improve the performance of the ESC. Since the project is done under limited resources and time, there is room to improve in a few aspects, such as building a full-scale car-trailer prototype and implementing an advanced control strategy for the ESC.
